

# Importing into Remix

---

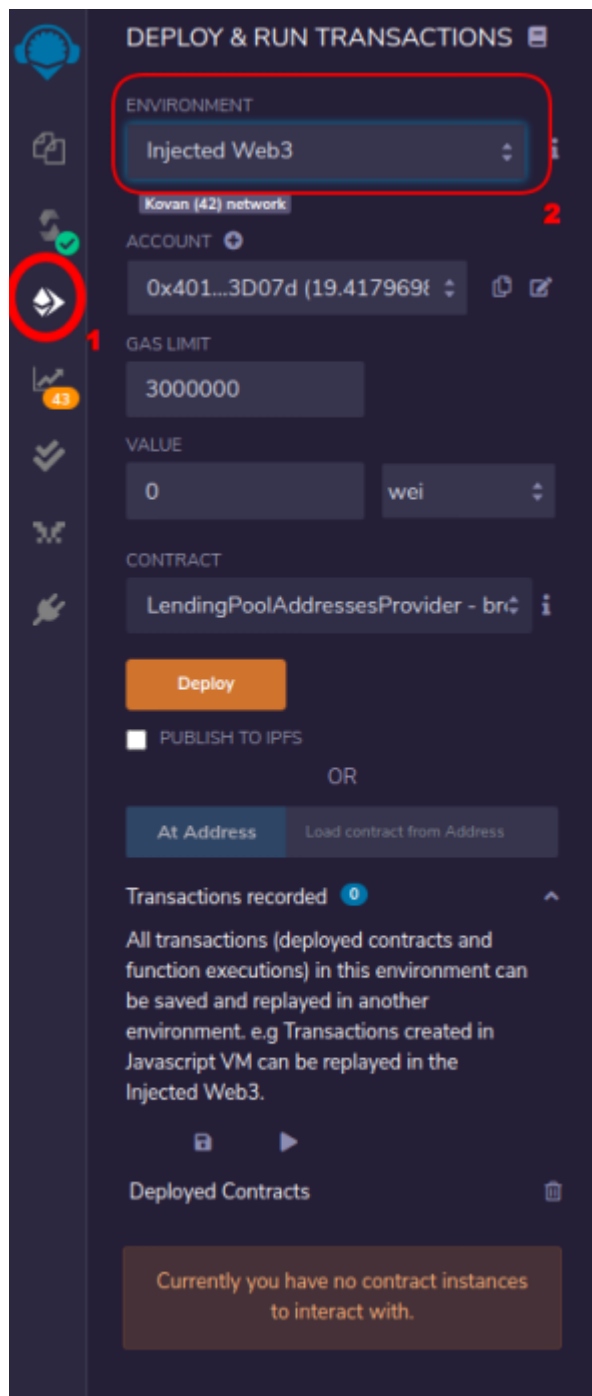

1. You'll need to create a blank file in Remix. This allows you to add directories
2. Create all the top level directories and treat the node dependencies like openzeppelin-solidity as a top level contract  
For instance, the contracts often import "openzeppelin....". Change this to "./openzeppelin..." then create a directory in remix with that name and copy accross everything from the node\_modules
3. Add the subdirectories to your main directors. At this point you shouldn't have added any code.
4. Add the files and copy in the code.
5. Remember to change the openzeppelin-solidity import references to use relative paths.
6. Compile each file to check that you've imported correctly.  
->pro tip: when you get an error about a contract having already been declared, look at the import above the offending line. Go to that file. One of the imports in this file has an incorrect path

# Deploying to Kovan from remix

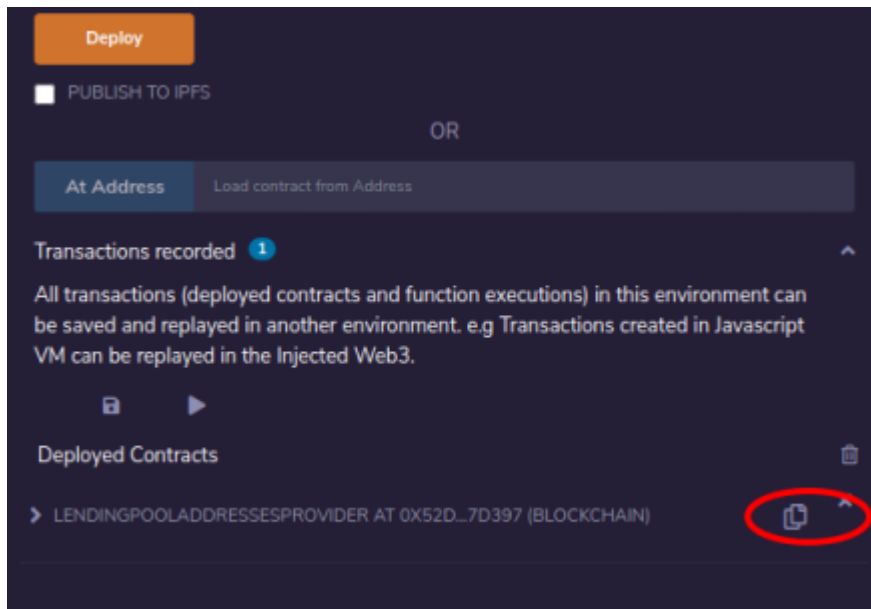

---

The first step to deploying is to find the innermost contract in the Aave architecture. In Aave there's a contract registry that is deployed once. All the contracts reference this registry contract to retrieve the correct versions of their dependencies.

To deploy, click on the deploy menu option (1) and set Environment to Injected Web3 (2). This will prompt your metamask to connect to Remix.

Deploy LendingPoolAddressesProvider.sol:  
Your deployed contract will be displayed in a list.

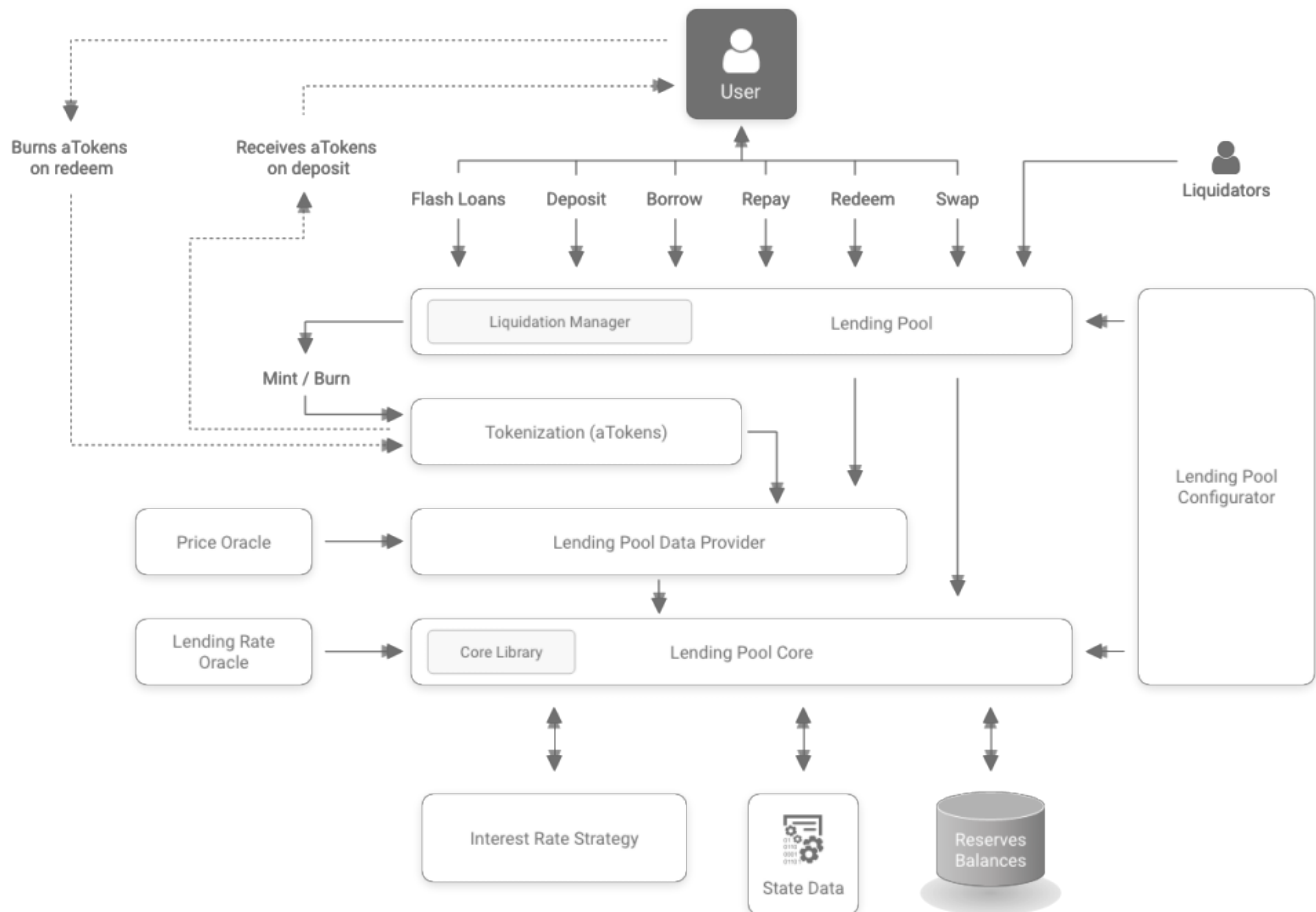

Click the copy icon to retrieve the address. Don't worry about ABIs. The repository has them already.

**Note: all deployments are happening from 0x4011Ba13ACD2E078B0234C125D04e5C61803D07d. Since many of these contracts are owned, ownership transfer will have to occur at some point. In addition to the owner, the contracts have a role `LendingPoolManager`. This is a human controlled account that has authority to control vital actions at the core of the protocol.**

```
LendingPoolAddressesProvider Kovan address:  
0x1a84C655a3F178BeA02DcBc9F46Bc84c17c36FC0
```

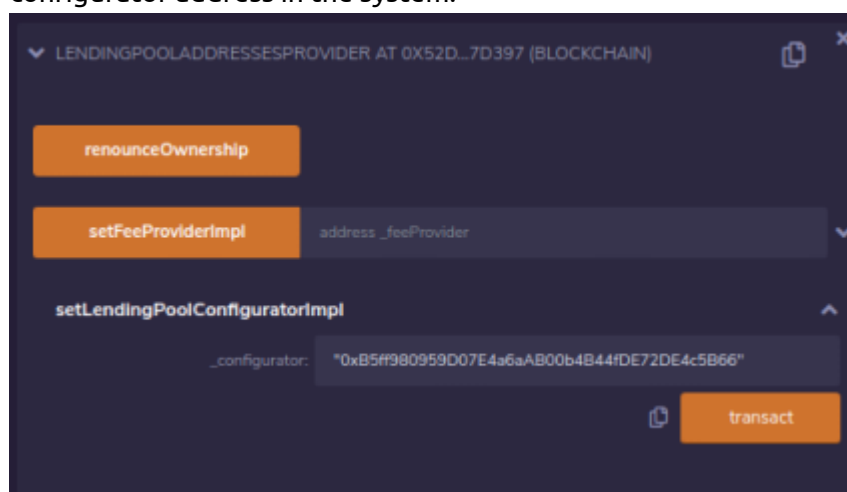

Next we should look at all the expected contracts in `LendingpoolAddressesProvider` and deploy them and their dependencies.

We'd have to start with their dependencies first. The best dependencies to start with are those that have none. The diagram below is the core architecture of the Aave smart contracts:

let's start the LendingPoolConfigurator. This contract was written before EIP-170 which sets an upper limit on contract size. To get around this, we set Remix to optimize compile.

We initially get an address for LendingPoolConfigurator. We inform LendingPoolAddress provider of its existence by calling the set function for Configurator. This spawns a new proxy contract. If we call LendingPoolAddressProvider.getLendingPoolConfigurator, we now get a new address. This is the configurator address in the system.

LendingPoolConfigurator: 0xF1bEF1a345371716B607590003f2aBC180C7036C

Following the steps above,

```
LendingPoolParametersProvider: 0x71B78196dFB678A6B796AfaBFe629a1A42BCD32d
```

We'll continue to deploy and initialize all the contracts listed at the top of `lendingPoolAddressProvider`. Note that some of the contracts aren't wrapped in proxies so the address won't change on set.

```

**/

contract LendingPoolAddressesProvider is Ownable {
    //events
    event LendingPoolUpdated(address indexed poolAddress);
    event LendingPoolCoreUpdated(address indexed coreAddress);
    event LendingPoolParametersProviderUpdated(address indexed parametersProviderAddress);
    event LendingPoolManagerUpdated(address indexed managerAddress);
    event LendingPoolConfiguratorUpdated(address indexed configuratorAddress);
    event LendingPoolLiquidationManagerUpdated(address indexed liquidationManagerAddress);
    event LendingPoolDataProviderUpdated(address indexed dataProviderAddress);
    event EthereumAddressUpdated(address indexed ethereumAddress);
    event PriceOracleUpdated(address indexed priceOracleAddress);
    event LendingRateOracleUpdated(address indexed rateOracleAddress);
    event FeeProviderUpdated(address indexed feeProviderAddress);
    event TokenDistributorUpdated(address indexed tokenDistributorAddress);
}

```

```

LendingPool: 0x667091e8c1FA63977C1Ce99Ae5653Af677C17655
LendingPoolCore: 0x6444Bff5143F4722A47877774A39dD9250D529A5
LendingPoolConfigurator: 0xF1bEF1a345371716B607590003f2aABC180C7036C
LendingPoolParametersProvider: 0x71B78196dFB678A6B796AfaBFe629a1A42BCD32d
LendingPoolManager: this is a wallet address (preferably multisig). For
simplicity, I've set it to your address
LendingPoolLiquidationManager: 0xb0A659f600Ef834BA2c172EA790243bCAbe098ed
LendingPoolDataProvider: 0x9e5d3229359eB3640D60066cBb1de83F216158CE
EthereumAddress - unused in this contract
PriceOracle -> first deployed the provided mock PriceOracle:
0x31DAe81A5c6C435f8d7d43990822775181bA1403
LendingRateOracle: 0xDF9DD372dfd530972e776E91b4C9baD7d334F741
FeeProvider: 0xdd42eb4633aAE0609f72D8163edDa309f2E0f4c6
TokenDistributor: 0x8b48d8eE7B81988df5321f62a73Cb0AaD2B1F412

```

Note on the price oracle: I've given arbitrary values for the ETHUSD and Kovan Dai price so that zero isn't returned. Once the reserves are deployed, you can update for each token

We then add the addresses for all the mock contracts

First the MockAggregators

```

```

The LendingPoolcore links to a library called the core library. a library is a stateless contract that provides helper functions. A very common library in use is OpenZeppelin's SafeMath which provides basic arithmetic functions that don't allow unsigned integer under- or overflows

```
CoreLibrary: 0x98Bc70e12eCd10Bf7dd52c27003703A6F96bBFF5
```

## Aave terminology

When an ERC20 token is added to Aave for deposits and loans, it is referred to as a reserve. Each reserve requires it's own ReserveInterestRateStrategy contract.

This contract informs Aave how to set borrowing and savings rates. I've deployed one for the Kovan Dai token as an example:

```
ReserveInterestRateStrategy for Dai:
0x2963bF52c63935CDa43aD774e1E2B126A81594FE
Kovan Dai: 0xc4375b7de8af5a38a93548eb8453a498222c4ff2
```

## Reserve initialization

---

To begin using Aave, we have to initialize the reserves so that deposits, borrows and liquidations can occur. This section outlines the process adding an asset as a reserve. Only a LendingPoolManager account can add a reserve to the system.

### InterestRateStrategy

Each reserve has a corresponding contract that determines the interest rate strategy for that reserve. Before initializing the reserves, we need to deploy this InterestRateStrategyContract for each reserve. Take note that the interest rate fields are expressed in RAY units. 1 RAY is equal to  $10^{27}$ . So if you want to set an interest rate of 20% then you'll supply the value of  $0.2 \cdot 10^{27}$  as the parameter value.

## Lending Rate and Price Oracles

While oracles should be updated in real time, it won't hurt to initialize them with non-zero values for each asset for debugging purposes. The Lending Rate values are RAY but the price values are WAD.  $1 \text{ WAD} = 10^{18}$ , the same precision as Ether and most ERC20 tokens. Bear in mind that on mainnet WBTC has 8 decimal places.

## Initialize Reserve

The LendingPoolConfigurator provides a method to initialize a reserve. In the process, the corresponding AToken is deployed. LendingPoolCore provides getReservATokenAddress which takes the base token as the sole parameter. After initializing, the following AToken addresses were retrieved:

```
ABAT: 0x07A9B5280Ca782D413B4f10Cd5dce82b1Df6977d

```

## Mint reserve tokens for user

The next task would be to mint some token to deposit. In remix, you can deploy a contract to an existing address. Recompile a mock token such as MockDAI and paste the existing MockDai address in the at textbox. Then mint an amount to deposit.

The mock token addresses are:

```
MockBAT": "0x719d113f2c0D11f9797c3BC8D261323820c2132e
MockDAI": "0x6DCBFbcd99D7b989De348aC06c8944Aa4738192a

MockZRX": "0x42Df5A2E1b0Be4CA0936dDD5d73A8c29D7b90335
```

## Activate Reserves

Before actions on a reserve can happen, they have to be activated. `LendingPoolConfigurator` has the `activateReserve` function.

## Enable Borrowing

`LendingPoolConfigurator` is required once more to enable borrowing on the reserve.

`LendingPoolCore` is required to enable the reserve to be used as collateral

## ERC20.Approve

If the token is not eth, you first have to approve the `LendingPoolCore` address before depositing. The address can be retrieved from the `LendingPoolAddressesProvider`.
